

1 Exercise 1

We consider a finite set of data points $\{(y_0(x_0), x_0), \dots, (y_{n-1}(x_{n-1}), x_{n-1})\}$ and the following two vectors:

$$\begin{aligned} x^\top &= (x_0 \dots x_{n-1}) \\ y^\top &= (y_0, \dots y_{n-1}) \end{aligned}$$

Furthermore we assume that there exist a continuous function f and a normal distributed error $\epsilon_i \propto N(0, \sigma^2)$ such that $\forall i$

$$y(x_i) = f(x_i) + \epsilon_i \quad (1)$$

We now approximate $f(x_i)$ with a polynomial

$$f(x_i) \approx \sum_{j=0}^p (x_i)^j \beta_j := \tilde{y} \quad (2)$$

s.t

$$y(x_i) = \tilde{y}(x_i) + \epsilon_i + \zeta_i \quad (3)$$

where ζ_i is the error of the approximation. This also can be written in a vectorial form

$$y(x) = A(x)\beta + \epsilon + \zeta \quad \text{with} \quad a_{ij} = (y_i)^j \quad (4)$$

where $\epsilon \in \mathbb{R}^n$, $\beta \in \mathbb{R}^p$ with $p \in \mathbb{N}$ and $A(x) \in \mathbb{R}^{n \times p}$ is called the feature Matrix. In the following we assume that we have only one error $\epsilon_i \propto N(0, \sigma^2)$

$$y = \tilde{y} + \epsilon \quad (5)$$

We now define

$$C(\beta) = \frac{1}{n} \sum_{i=0}^{n-1} (y_i - \tilde{y}_i)^2 = \frac{1}{n} \sum_{i=0}^{n-1} (y_i - \sum_{j=0}^{p-1} A_i^j \beta_j)^2 \quad (6)$$

to determine the quality of our approximation as a function of β_i . The optimal fit is given by the minima of that function:

$$\partial_{\beta_j} (C(\beta)) e_j = \frac{2}{n} (y^i - A_i^k \beta_k) A_i^j e_j \quad (7)$$

where e_j correspond to the eukledian basis vectors and the Einstein summation rule is used. Again one can express this in Matrix form:

$$\begin{pmatrix} \partial_{\beta_0} C(\beta) \\ \vdots \\ \partial_{\beta_{p-1}} C(\beta) \end{pmatrix} = \begin{pmatrix} (y_0 - A_0^k \beta_k) A_0^0 + \dots + (y_{n-1} - A_{n-1}^k \beta_k) A_{n-1}^0 \\ \vdots \\ (y_0 - A_0^k \beta_k) A_0^{p-1} + \dots + (y_{n-1} - A_{n-1}^k \beta_k) A_{n-1}^{p-1} \end{pmatrix} = \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix} \quad (8)$$

By definining the following vector

$$a_i = A_k^i e^k \quad (9)$$

this simplyfies to

$$\begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix} = \begin{pmatrix} (a_0, y) - (a_0, A\beta) \\ \vdots \\ (a_{p-1}, y) - (a_{p-1}, A\beta) \end{pmatrix} = A^\top (y - A\beta) \quad (10)$$

where (\cdot, \cdot) corresponds to the standard scalarproduct. The parameters of the approximation with the smallest error ϵ are thus given by

$$\tilde{\beta} = (A^\top A)^{-1} A^\top y \quad (11)$$

We now look at some statistical quantities. For that note that the following two relations with X_1 and X_2 beeing two random variables and $\lambda \in \mathbb{R}^{n \times m}$ a constant hold:

$$\mathbb{E}[\lambda \cdot (X_1 + X_2)] = \lambda \cdot (\mathbb{E}[X_1] + \mathbb{E}[X_2]) \quad (12)$$

$$\text{var}[\lambda \cdot X_1] = \lambda \lambda^\top \cdot \text{var}[X_1] \quad (13)$$

With this we get the following expectation values and variances for y_i

$$\mathbb{E}(y_i) = \mathbb{E}[A_i^j \beta_j + \epsilon_i] = \mathbb{E}[A_i^j \beta_j] + \mathbb{E}[\epsilon_i] = A_i^j \beta_j \quad (14)$$

$$\text{var}(y_i) = \mathbb{E}[(y_i - \mathbb{E}(y_i))^2] = \mathbb{E}[(A_i^j \beta_j + \epsilon_i - A_i^j \beta_j)^2] = \mathbb{E}[\epsilon_i^2] = \text{var}(\epsilon_i) = \sigma^2 \quad (15)$$

Therefore $y \propto N(A_i^j \beta_j, \sigma^2)$ and thus y follows a normal distribution $N(A\beta, \sigma^2)$. The expectation value and variance of the ideal parameters $\tilde{\beta}$ are then given by

$$\mathbb{R}[\tilde{\beta}] = \mathbb{E}[(A^\top A)^{-1} A^\top y] = (A^\top A)^{-1} A^\top \mathbb{E}[y] = (A^\top A)^{-1} (A^\top A) \beta = \beta \quad (16)$$

$$\text{var}[\tilde{\beta}] = \text{var}[(A^\top A)^{-1} A^\top y] = (A^\top A)^{-1} A^\top ((A^\top A)^{-1} A^\top)^\top \text{var}[y^2] \quad (17)$$

$$= (A^\top A)^{-1} A^\top A ((A^\top A)^\top)^{-1} \text{var}[y^2] \quad (18)$$

$$= (A^\top A)^{-1} \text{var}[y^2] = \sigma^2 (A^\top A)^{-1} \quad (19)$$
